Mean Field Inference

Joint Distribution

Let X and Z be random variables. A generative model is any model that defines a joint distribution over these variables.

Joint Distribution

Let X and Z be random variables. A generative model is any model that defines a joint distribution over these variables.

3 Examples of Generative Models

- p(x,z) = p(x)p(z|x)
- p(x,z) = p(z)p(x|z)
- p(x,z) = p(x)p(z)

Likelihood and prior

From here on, x is our observed data. On the other hand, z is an unobserved outcome.

- p(x|z) is the **likelihood**
- p(z) is the **prior** over Z

Notice: both distributions may depend on a non-random quantity α (write e.g. $p(z|\alpha)$). In that case, we call α a hyperparameter.

$$p(z|x) = \frac{p(x|z)p(z)}{p(x)}$$

$$p(z|x) = \frac{\overbrace{p(x|z)}^{\text{likelihood prior}} \overbrace{p(z)}^{\text{prior}}}{p(x)}$$

$$\underbrace{p(z|x)}_{\text{posterior}} = \underbrace{\frac{p(x|z)}{p(x)}}_{\text{likelihood}} \underbrace{\frac{prior}{p(z)}}_{p(x)}$$

$$\underbrace{p(z|x)}_{\text{posterior}} = \frac{\underbrace{p(x|z)}_{p(x)} \underbrace{p(z)}_{p(z)}}{\underbrace{p(x)}_{\text{marginal likelihood/evidence}}}$$

We want to compute the posterior over latent variables p(z|x). This involves computing the marginal likelihood

$$p(x) = \int p(x,z) dz$$

which is often **intractable**. This problem motivates the use of **approximate inference** techniques.

Bayesian Inference

Model parameters θ are also random. The generative model becomes

- ▶ $p(x, \theta)$ for fully observed data (supervised learning)
- $p(x, z, \theta)$ for observed and latent data (unsupervised learning)

Bayesian Inference

The evidence becomes even harder to compute because θ is often high-dimensional (just think of neural nets!).

- $p(x) = \int p(x, \theta) d\theta$ (supervised learning)
- $p(x) = \int \int p(x, z, \theta) dz d\theta$ (unsupervised learning)

Bayesian Inference

The evidence becomes even harder to compute because θ is often high-dimensional (just think of neural nets!).

- $p(x) = \int p(x, \theta) d\theta$ (supervised learning)
- $p(x) = \int \int p(x, z, \theta) dz d\theta$ (unsupervised learning)

Again, approximate inference is needed.

Relationship to EM
Variational Bayes

Mean Field Inference

We cannot compute the posterior when

- 1. The functional form of the posterior is unknown (we don't know which parameters to infer)
- 2. The functional form is known but the computation is intractable

Bayesian Logistic Regression

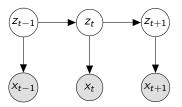

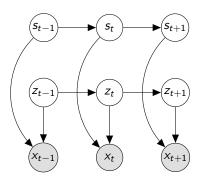

The Normal distribution is not conjugate to the Gibbs distribution. The form of the posterior is unknown.

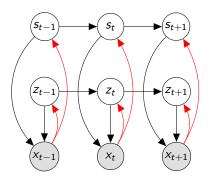

Bayesian Logistic Regression

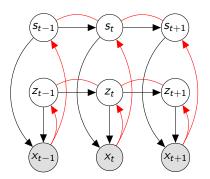

Intuition

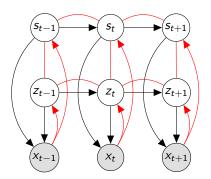

Simply assume that the posterior is Gaussian.

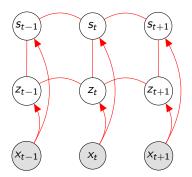

Inference network for FHHMs.

- M Markov chains over latent variables.
- L outcomes per latent variable.
- Sequence of length T.
- ► Complexity of inference: $\mathcal{O}(L^{2M}T)$.

FHMMs have several Markov chains over latent variables.

- M Markov chains over latent variables.
- L outcomes per latent variable.
- Sequence of length T.
- ▶ Complexity of inference: $\mathcal{O}(L^{2M}T)$.

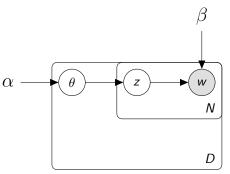

Intractable

Exponential dependency on the number of hidden Markov chains.

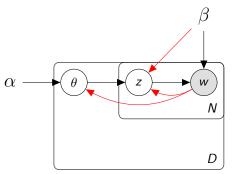

Intuition

Simply assume that the posterior consists of independent Markov chains.

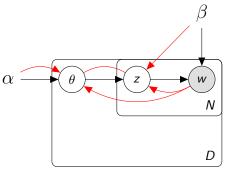

An admixture model that changes its mixture weights per document. We assume that the mixture components are fixed.

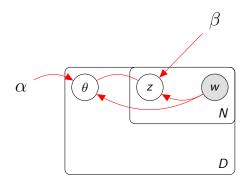

An admixture model that changes its mixture weights per document. We assume that the mixture components are fixed.

An admixture model that changes its mixture weights per document. We assume that the mixture components are fixed.

Inference network for LDA.

An admixture model that changes its mixture weights per document. Here we assume that the mixture components are fixed.

- D documents.
- N tokens and latent variables per document.
- L outcomes per latent variable.
- ▶ Complexity of inference: $\mathcal{O}(L^{DN})$.

Intuition

Simply assume that the posterior consists of independent categorical and Dirichlet distributions.

Intuition

Simply assume that the posterior consists of independent categorical and Dirichlet distributions.

Rule of Thumb

Simply assume that the posterior is in the same family as the prior.

Mean Field Inference

The Goal

Assume p(z|x) is not computable.

The Goal

Assume p(z|x) is not computable.

Idea

Let's approximate it by an auxiliary distribution q(z) that is computable!

The Goal

Assume p(z|x) is not computable.

Idea

Let's approximate it by an auxiliary distribution q(z) that is computable!

Requirement

Choose q(z) as close as possible to p(z|x) to obtain a faithful approximation.

The Kullback-Leibler divergence (or relative entropy) measures the divergence of a distribution q from a distribution p.

The Kullback-Leibler divergence (or relative entropy) measures the divergence of a distribution q from a distribution p.

► KL $(q(z) || p(z|x)) = \int q(z) \log \left(\frac{q(z)}{p(z|x)}\right) dz$ (continuous)

The Kullback-Leibler divergence (or relative entropy) measures the divergence of a distribution q from a distribution p.

- ► KL $(q(z) || p(z|x)) = \int q(z) \log \left(\frac{q(z)}{p(z|x)}\right) dz$ (continuous)
- ► KL $(q(z) || p(z|x)) = \sum_{z} q(z) \log \left(\frac{q(z)}{p(z|x)}\right)$ (discrete)

The Kullback-Leibler divergence (or relative entropy) measures the divergence of a distribution q from a distribution p.

- ► KL $(q(z) || p(z|x)) = \int q(z) \log \left(\frac{q(z)}{p(z|x)}\right) dz$ (continuous)
- ► KL $(q(z) || p(z|x)) = \sum_{z} q(z) \log \left(\frac{q(z)}{p(z|x)}\right)$ (discrete)
- $\mathsf{KL}\left(q(z) \mid\mid p(z|x)\right) = \mathbb{E}_{q(z)}\left[\log\left(\frac{q(z)}{p(z|x)}\right)\right]$ (both)

Properties

► KL $(q(z) || p(z|x)) \ge 0$ with equality iff q(z) = p(z|x).

Properties

- ► KL $(q(z) || p(z|x)) \ge 0$ with equality iff q(z) = p(z|x).
- $\mathsf{KL}\left(q(z) \mid\mid p(z|x)\right) = \mathbb{E}_{q(z)}\left[\log\left(\frac{p(z|x)}{q(z)}\right)\right] \leq 0.$

Properties

- ► KL $(q(z) || p(z|x)) \ge 0$ with equality iff q(z) = p(z|x).
- KL $(q(z) \mid\mid p(z|x)) = \mathbb{E}_{q(z)} \left[\log \left(\frac{p(z|x)}{q(z)} \right) \right] \le 0.$
- ► KL $(q(z) || p(z|x)) = \infty$ if $\exists z \text{ s.t. } p(z|x) = 0 \text{ and } q(z) > 0.$

Properties

- ► KL $(q(z) || p(z|x)) \ge 0$ with equality iff q(z) = p(z|x).
- KL $(q(z) \mid\mid p(z|x)) = \mathbb{E}_{q(z)} \left[\log \left(\frac{p(z|x)}{q(z)} \right) \right] \le 0.$
- ► KL $(q(z) || p(z|x)) = \infty$ if $\exists z \text{ s.t. } p(z|x) = 0 \text{ and } q(z) > 0.$
- ▶ In general $\mathsf{KL}\left(q(z)\mid\mid p(z|x)\right) \neq \mathsf{KL}\left(p(z|x)\mid\mid q(z)\right)$.

$$\log p(x) = \log \left(\int p(x,z) dz \right)$$

$$\log p(x) = \log \left(\int p(x, z) dz \right)$$
$$= \log \left(\int \frac{q(z)}{q(z)} \frac{p(x, z)}{q(z)} dz \right)$$

$$\log p(x) = \log \left(\int p(x, z) dz \right)$$

$$= \log \left(\int q(z) \frac{p(x, z)}{q(z)} dz \right)$$

$$\geq \int q(z) \log \left(\frac{p(x, z)}{q(z)} \right) dz$$

$$\log p(x) = \log \left(\int p(x, z) dz \right)$$

$$= \log \left(\int \frac{q(z)}{q(z)} \frac{p(x, z)}{q(z)} dz \right)$$

$$\geq \int \frac{q(z)}{q(z)} \log \left(\frac{p(x, z)}{q(z)} \right) dz$$

$$= \int \frac{q(z)}{q(z)} \log \left(\frac{p(z|x)p(x)}{q(z)} \right) dz$$

$$\log p(x) = \log \left(\int p(x, z) dz \right)$$

$$= \log \left(\int \frac{q(z)}{q(z)} \frac{p(x, z)}{q(z)} dz \right)$$

$$\geq \int \frac{q(z)}{q(z)} \log \left(\frac{p(x, z)}{q(z)} \right) dz$$

$$= \int \frac{q(z)}{q(z)} \log \left(\frac{p(z|x)p(x)}{q(z)} \right) dz + \log p(x)$$

$$\log p(x) \ge \int q(z) \log \left(\frac{p(z|x)}{q(z)}\right) dz + \log p(x)$$

$$\log p(x) \ge \int q(z) \log \left(\frac{p(z|x)}{q(z)}\right) dz + \log p(x)$$

$$= - \mathsf{KL}\left(q(z) \mid\mid p(z|x)\right) + \log p(x)$$

$$\log p(x) \ge \int q(z) \log \left(\frac{p(z|x)}{q(z)}\right) dz + \log p(x)$$

$$= - \mathsf{KL}\left(q(z) \mid\mid p(z|x)\right) + \log p(x)$$

We have derived a lower bound on the log-evidence whose gap is exactly KL(q(z) || p(z|x)).

Recall that we want to find q(z) such that $\mathrm{KL}\,(q(z)\mid\mid p(z|x))$ is small.

Recall that we want to find q(z) such that KL(q(z) || p(z|x)) is small. Formal Objective

$$\min_{q(z)} \mathsf{KL}\left(q(z) \mid\mid p(z|x)\right)$$

Recall that we want to find q(z) such that $\mathsf{KL}\left(q(z)\mid\mid p(z|x)\right)$ is small.

Formal Objective

$$\min_{q(z)} \mathsf{KL}\left(q(z) \mid\mid p(z|x)
ight) = \max_{q(z)} - \mathsf{KL}\left(q(z) \mid\mid p(z|x)
ight)$$

$$\max_{q(z)} - \mathsf{KL}\left(q(z) \mid\mid p(z|x)\right)$$

$$\max_{q(z)} - KL(q(z) || p(z|x))$$

$$= \max_{q(z)} \int q(z) \log \left(\frac{p(z|x)}{q(z)}\right) dz$$

$$\max_{q(z)} - KL(q(z) || p(z|x))$$

$$= \max_{q(z)} \int q(z) \log \left(\frac{p(z|x)}{q(z)}\right) dz$$

$$= \max_{q(z)} \int q(z) \log \left(\frac{p(z,x)}{p(x)q(z)}\right) dz$$

$$\begin{aligned} & \max_{q(z)} - \mathsf{KL}\left(q(z) \mid\mid p(z|x)\right) \\ &= \max_{q(z)} \int q(z) \log \left(\frac{p(z|x)}{q(z)}\right) \mathrm{d}z \\ &= \max_{q(z)} \int q(z) \log \left(\frac{p(z,x)}{p(x)q(z)}\right) \mathrm{d}z \\ &= \max_{q(z)} \int q(z) \log \left(p(z,x)\right) \mathrm{d}z - \int q(z) \log q(z) \mathrm{d}z - \overbrace{\log p(x)}^{constant} \end{aligned}$$

$$\max_{q(z)} - KL (q(z) || p(z|x))$$

$$= \max_{q(z)} \int q(z) \log \left(\frac{p(z|x)}{q(z)}\right) dz$$

$$= \max_{q(z)} \int q(z) \log \left(\frac{p(z,x)}{p(x)q(z)}\right) dz$$

$$= \max_{q(z)} \int q(z) \log (p(z,x)) dz - \int q(z) \log q(z) dz - \overbrace{\log p(x)}^{constant}$$

$$= \max_{q(z)} \mathbb{E}_{q(z)} [\log p(x,z)] + \mathbb{H} (q(z))$$

As before, we have derived a lower bound on the log-evidence. This **evidence lower bound** or **ELBO** is our optimisation objective.

ELBO

$$\max_{q(z)} \mathbb{E}_{q(z)} \left[\log p(x,z) \right] + \mathbb{H} \left(q(z) \right)$$

Performing VI (Frequentist Case)

VI in its basic form can be performed via coordinate ascent. This can be done as a 2-step procedure.

Performing VI (Frequentist Case)

VI in its basic form can be performed via coordinate ascent. This can be done as a 2-step procedure.

1. Maximize (regularised) expected log-density.

$$\max_{q(z)} \mathbb{E}_{q(z)} \left[\log \left(p(x,z)
ight)
ight] + \mathbb{H} \left(q(z)
ight)$$

VI in its basic form can be performed via coordinate ascent. This can be done as a 2-step procedure.

1. Maximize (regularised) expected log-density.

$$\max_{q(z)} \mathbb{E}_{q(z)} \left[\log \left(p(x,z) \right) \right] + \mathbb{H} \left(q(z) \right)$$

2. Optimise generative model.

$$\max_{p(x,z)} \mathbb{E}_{q(z)} \left[\log \left(p(x,z) \right) \right] + \underbrace{\mathbb{H} \left(q(z) \right)}_{\text{constant}}$$

Recap: EM Algorithm

```
E-step Compute: \mathbb{E}_{p(z|x)} [\log (p(x,z))]. Same as: \max_{p(z|x)} \mathbb{E}_{p(z|x)} [\log p(x,z)]

M-step \max_{p(x,z)} \mathbb{E}_{p(z|x)} [\log p(x,z)] + \underbrace{\mathbb{H}(p(z|x))}_{\text{constant}}
```

Recap: EM Algorithm

E-step Compute:
$$\mathbb{E}_{p(z|x)} [\log (p(x,z))]$$
. Same as: $\max_{p(z|x)} \mathbb{E}_{p(z|x)} [\log p(x,z)]$

M-step $\max_{p(x,z)} \mathbb{E}_{p(z|x)} [\log p(x,z)] + \underbrace{\mathbb{H} (p(z|x))}_{\text{constant}}$

EM is variational inference!

$$q(z) = p(z|x)$$

$$KL(q(z) || p(z|x)) = 0$$

Performing VI (Bayesian Case)

We have latent variables z (e.g. POS tags) and θ (e.g. model parameters).

1. Maximise over local variables z.

$$\max_{q(z)} \mathbb{E}_{q(z)q(\theta)} \left[\log p(x,z,\theta) \right] + \mathbb{H} \left(q(z) \right)$$

Performing VI (Bayesian Case)

We have latent variables z (e.g. POS tags) and θ (e.g. model parameters).

1. Maximise over local variables z.

$$\max_{q(z)} \mathbb{E}_{q(z)q(\theta)} \left[\log p(x, z, \theta) \right] + \mathbb{H} \left(q(z) \right)$$

2. Maximise over global variables θ .

$$\max_{q(heta)} \mathbb{E}_{q(z)q(heta)} \left[\log p(x,z, heta)
ight] + \mathbb{H} \left(q(heta)
ight)$$

Differences between frequentist VI and VB (Variational Bayes)

- Frequentist VI optimises two sets of parameters, VB only optimises variational parameters
- Entropy term matters in the M-step for VB but not for VI

Generative Models

Examples

Variational Inference
Deriving VI with Jensen's Inequality

Relationship to EM
Variational Bayes

Mean Field Inference

Designing a tractable approximation

- Recall: The approximation q(z) needs to be tractable.
- ► Common solution: make **all** latent variables independent under q(z).

Designing a tractable approximation

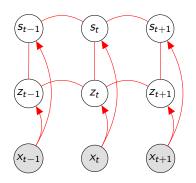

- Recall: The approximation q(z) needs to be tractable.
- Common solution: make all latent variables independent under q(z).
- ▶ Formal assumption: $q(z) = \prod_{i=1}^{N} q(z_i)$

Designing a tractable approximation

- Recall: The approximation q(z) needs to be tractable.
- ► Common solution: make **all** latent variables independent under q(z).
- Formal assumption: $q(z) = \prod_{i=1}^{N} q(z_i)$

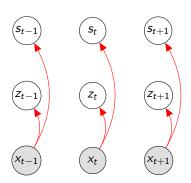

This approximation strategy is commonly known as **mean field** approximation.

Original FHHM Inference

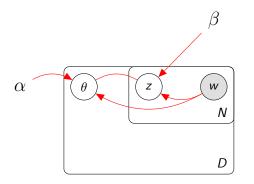

Exact posterior p(s, z|x)

Mean field FHHM Inference

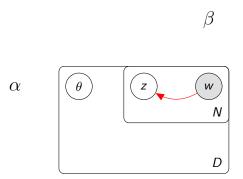

Approximate posterior
$$q(s,z) = \prod_{t=1}^T q(s_t) q(z_t)$$

Original LDA Inference

Exact posterior $p(z, \theta|w, \alpha, \beta)$

Mean field LDA Inference

Approximate posterior
$$q(z, \theta|w, \alpha, \beta) = \prod_{d=1}^{D} q(\theta_d) \prod_{i=1}^{N} q(z_i|w)$$

Summary

- Posterior inference is often intractable because the marginal likelihood (or evidence) p(x) cannot be computed efficiently.
- Variational inference approximates the posterior p(z|x) with a simpler distribution q(z).
- ▶ The variational objective is the **evidence** lower bound (ELBO):

$$\mathbb{E}_{q(z)}\left[\log\left(p(x,z)\right)\right] + \mathbb{H}\left(q(z)\right)$$

Summary

- ► The **ELBO** is a lower bound on the log-evidence.
- ▶ When q(z) = p(z|x) we recover EM.
- A common approximation is the **mean field** approximation which assumes that all latent variables are independent:

$$q(z) = \prod_{i=1}^{N} q(z_i)$$
